

# ASHES, Vol. 5(3) - The no-nicotine blues: Investigating why some smokers feel depressed while trying to quit

April 1, 2009

Recent research has identified a correlation between nicotine withdrawal and depression. Scientists suggest that this association is related to changes in the function of serotonin transporter proteins, known to play a role in regulating mood, during periods of nicotine abstinence. This week's ASHES reviews an animal study investigating both the biological mechanisms underlying the appearance of depressive signs, and a potential treatment (Semba & Wakuta, 2008).

## Methods

- Researchers implanted adult male rats with a pump that administered either nicotine or a neutral solution (control) at a constant rate for a period of 12 days.
- A separate group of rats also received bupropion treatment at 15 or 30mg/kg/day in addition to the nicotine or control treatments.
- Researchers removed the pumps and either (1) decapitated rats on the last day of treatment or (2) allowed the rats to enter into a withdrawal state, which lasted for an additional two days.
- Researchers prepared slides of rats' brain tissue, including the dorsal raphe nuclei.
- [in situ hybridization](#) was performed to locate the mRNA that codes for serotonin transporter proteins.
- Researchers used computer software to create photographic images from the in situ slides.
- Scientists measured the relative [optical density](#) of the slides; this distinguishes areas positive for serotonin transporter mRNA from the rest of the brain tissue because this transporter appears darker than areas that do not contain it.

- Scientists compared the relative optical densities of the experimental and control groups' slides using a t-test as the statistical tool.

## Results

- As Figure 1 shows, expression of serotonin transporter coding mRNA in the dorsal raphe nuclei of rats exposed to nicotine for 12 days was significantly decreased (-24%) when compared to the control,  $t(15) = 3.18$ ,  $p < 0.01$ , immediately after nicotine administration was stopped.
- Two days following the termination of nicotine administration scientists identified a lesser, but still significant decrease (-14.9%), expression compared to the control,  $t(14) = 2.36$ ,  $p < 0.05$ .
- As Figure 2 shows, rats who were co-administered bupropion showed smaller decreases in serotonin transporter coding mRNA; the higher the dose, the smaller the decrease observed.

## Limitations

- Findings from animal models do not always generalize to human beings. The way nicotine effects the expression of serotonin transporter mRNA might vary across species.
- The synthesis of mRNA, which codes for serotonin transporter proteins, and the actual expression of these proteins is not always the same.
- Several similar studies have found no significant difference between control and experimental conditions. However, these studies used different tissue preparations and/or adolescent rats instead of adult rats. These differences in design could account for differences in results observed.
- Researchers are unsure how long the decrease in the expression of transporter coding mRNA lasts, and whether or not the change is permanent due to the fact that the [in situ hybridization](#) was not performed in live tissue.
- Biological processes and subjective states might not be consistent. In other words, reduced serotonin function might not cause depressed mood in rats as it does in humans.

## Conclusions

Chronic exposure to nicotine can reduce the amount of serotonin transporter protein coding mRNA present in the dorsal raphe nuclei of rats. This reduction might underlie the feelings of depression that humans sometimes report while trying to abstain from smoking, making it very difficult for them to stop using products containing nicotine. Co-administration of Bupropion appears to help

relieve this circumstance, and might be a useful tool to help smokers quit.
